

Artificial digestion to detect *T. spiralis* larvae in pork

Trichinella spiralis widespread in wild animals and often can be found in domestic pigs. This parasite species is also the most important etiological agent in human trichinosis. This study aimed to compare the detection capability (for *Trichinella spiralis* larvae) of artificial digestion to an experimental microfluidic device.

Methodology

A total of 10 positive domestic pigs for *T. spiralis* were tested (5g/animal) in both methods. Artificial digestion is the gold standard method for the direct detection of *Trichinella* larvae in meat samples. The microfluidic method is a new approach regarding the detection of *Trichinella* spp. This method was done by an experimental device from Hungary (Bionics Biomicrofluidics lab, Budapesta).

The detection of *Trichinella* spp.larvae

Trichinella spp. larvae from artificial digestion

Out of the 10 positive samples, only two animals were negative in the microfluidic method, but they were positive (2, 21 larvae) in artificial digestion. Samples with high (500, 100, 75, 68) and medium (58, 20) number of larvae in artificial digestion, had a medium (200, 19, 40, 51) and small (4, 1) larvae count in the microfluidic method.

Conclusion

In two cases, the number of larvae found in the microfluidic method was higher (35, 18) than in artificial digestion (32, 12).
